

APPLICATION FOR
UNITED STATES LETTERS PATENT

for the invention of a

ADJUSTABLE BROADBAND ANTENNA

BE IT KNOWN THAT I, Henry D. Kallina, a citizen of the
United States of America, have invented new and useful
improvements in an ADJUSTABLE BROADBAND ANTENNA of which the
following is a specification.

ADJUSTABLE BROADBAND ANTENNA

REFERENCE TO RELATED APPLICATIONS:

This application is a continuation of my application having serial number 09/467,639, filed December 20, 1999, now U.S. Patent No. _____, which is a continuation of my application having serial number 09/001,697, filed December 31, 1997, now U.S. Patent 6,005,518, both of which are incorporated herein in their entirety by reference.

FIELD OF THE INVENTION

This invention relates to a removable base for supporting an antenna on the roof of a vehicle.

BACKGROUND OF THE INVENTION

A continuing problem in high frequency communications networks, both in their installation and maintenance, is the necessity of assuring the integrity of the transmission line. This is particularly true in cable television systems where RF leaks in the CATV coaxial cable distribution networks can severely effect the quality of the received signal. Such leaks may be due to small cracks in the cable, loose fittings or other non-RF tight conditions.

The FCC requires that cable TV/LAN operators monitor their networks and calculate a Cumulative Leakage Index (CLI). The components of the CLI are the RF signal level, the distance from the coaxial cable, the frequency of the

1 signal, and the number of leaks per coax mile. The CLI is
2 calculated for a specific time period.

3 There are several licensed sources of RF energy in the
4 frequency range that is used by the CATV industry for video.
5 There are also unintended sources of RF energy in this
6 frequency range such as power grids and commercial microwave
7 ovens.

8 In the process of measuring the CLI it is essential to
9 include signals which are true leaks from the CATV system.
10 It is equally important to exclude those signals which are
11 not leakage from the CATV system.

12 Previous efforts to solve this and related problems are
13 covered in the following patents.

14 U.S. Pat. No. 5,294,937 (1994) to Osteen et al.
15 discloses a cable leakage detection system to be placed in a
16 moving vehicle. The system comprises a computer control and
17 storage unit connected to a GPS Receiver, an RF meter and a
18 hand held keypad. This device measures cable leakages and
19 stores the data with time and location information on a
20 floppy disk.

21 U.S. Pat. No. 4,413,229 (1983) to Grant discloses a
22 method and apparatus for remote indication of faults in
23 cable systems using an RF signal for fault detection.

24 U.S. Pat. No. 4,810,961 (1989) to Takahaski et al.
25 discloses a system to determine the RF leakage from an

1 electromagnetically shielded building. The system consists
2 of transmitters with a different frequency for each floor of
3 the building.

4 U.S. Pat. No. 4,072,899 (1978) to Shimp discloses an RF
5 leak detector for detecting leakages from CATV coaxial
6 cable lines. The RF leaks are detected by transmitting a
7 unique signal and using a narrow band Receiver to detect the
8 unique signal to thereby detect small amounts of RF leakages
9 from defective CATV coaxial cables. If there is a leak, a
10 unique recognizable audible tone will be detected.

11 U.S. Pat. No. 4,100,572 (1978) to Cochrane discloses a
12 method and apparatus to test transmission lines using pulses
13 of one nano-second duration.

14 A method used in the past to calculate the CLI is to
15 use an RF detector and measure the field strength of signals
16 in the frequency range of interest. However, because of the
17 proliferation of RF generating equipment, such as two-way
18 radios, florescent lights, and the like, erroneous
19 detections of RF leaks are often made.

20 Another prior art method to detect leaks in the CATV
21 system which eliminates the possibility of detecting
22 erroneous signals is to transmit a unique signal on the CATV
23 system. A narrow band Receiver is used to detect the unique
24 signal. This method can be used to identify leaks from the
25 CATV system in the presence of erroneous signals in the same

1 frequency range. The disadvantage of this method is that it
 2 requires the transmission of the test signal over the CATV
 3 system. The spectrum available on the CATV system is
 4 increasingly limited, hindering the use of this method.

5 There is a need for a device that can positively
 6 identify an RF signal in the range of interest as a leak.

7 The present invention will detect and positively
 8 identify an RF signal as a leak from the CATV system.

9 Further, the present invention will ignore RF signals that
 10 are not CATV leaks in the calculation of the CLI.

11 The present invention is an RF Receiver which can be
 12 mounted in a vehicle. The RF Receiver can be implemented
 13 with several options depending on the purpose of the vehicle
 14 (i.e. monitoring system health integrity or repair of
 15 defective components). The RF Receiver is a passive unit
 16 that requires no special test signals on the CATV system.
 17 The RF Receiver does not limit the speed of the vehicle.

18 An option of the invention used to aid in the location
 19 of the leak is an ability to determine if the leak is on the
 20 left or right side of the vehicle.

21

22 SUMMARY OF THE INVENTION

23 The main object of the present invention is to provide
 24 an RF leakage detector for the CATV industry which will
 25 unambiguously detect a leak in a cable system.

Patent 5,550,550

1 Another object of the present invention is to provide a
2 computerized calculation of the Cumulative Leakage Index
3 (CLI) or the Vehicular Leakage Index (VLI).

4 Another object of the present invention is to provide a
5 video detection signal functioning to positively identify a
6 signal as a leak from the CATV system.

7 Another object of the present invention is to provide
8 data display of the video signal showing an unambiguous
9 video signature.

10 Another object of the present invention is to detect if
11 the leak is on the left or right side of the vehicle which
12 is carrying the RF detector.

13 Another object of the present invention is to provide
14 data storage of the RF level of the detected leaks, the
15 time, date, and location of the leaks, the distance to the
16 coax cable, the RF frequency of the leak, the valid signal
17 detect, and the right/left location of the leak.

18 Other objects of this invention will appear from the
19 following description and appended claims, reference being
20 had to the accompanying drawings forming a part of this
21 specification wherein like reference characters designate
22 corresponding parts in the several views.

23 The preferred embodiment of the invention will have an
24 RF Receiver, a microprocessor, a Global Positioning System

1 Receiver, a deluxe control head, and an antenna capable of
2 detecting the direction to the leak.

3 The RF Receiver has the ability to tune to a TV channel
4 which is being transmitted by the CATV system. The RF
5 Receiver has within it both an AM Receiver and an FM
6 Receiver. The RF Receiver can be set to detect a signal of
7 a preset signal strength corresponding to the distance of
8 the vehicle from the cable. The RF Receiver can receive the
9 AM and the FM components of the tuned television channel.
10 The RF Receiver has the ability to correctly identify the
11 "signature" of a video signal which is leaking from the CATV
12 system by using the AM Receiver to detect the 15.734 Khz
13 horizontal sync. If there is no horizontal sync, the signal
14 is not video and will be ignored. If the sync is present,
15 the signal may be video and an LED will light on the front
16 panel indicating that the horizontal sync is present. The
17 device can further identify the leakage signal as video by
18 monitoring the 59.94 Hz vertical sync from the AM Receiver
19 with a speaker. An alternative method of identifying the
20 signal as the desired television channel (controlled by a
21 front panel switch) is to monitor the FM audio sound of the
22 tuned television signal on the speaker. The output of the FM
23 Receiver will be displayed on the light emitting diode
24 display meter.

1 The RF leakage detector can also be used to detect
2 signals other than television signals (i.e. carriers and the
3 like). Because the RF Receiver has within it an AM FM, and
4 FSK Receiver the modulation of the signals can be detected.
5 The detected results can be displayed on the deluxe control
6 head or stored by the microprocessor. The audio speaker and
7 the microprocessor can be used to validate the signal.

8 The signal level of the video and the signal level of
9 the sync will be displayed simultaneously on the meter. The
10 final indication that the signal is a video leak of the
11 tuned television channel will be a 3dB to 6dB difference
12 between the peak sync signal and the average video signal.

13 The microprocessor is used to collect data, process it,
14 and store the data in a memory device. The microprocessor
15 has ports to be used to download the collected data. The
16 microprocessor is interfaced with the Receiver and can be
17 further interfaced with the speedometer cable of the vehicle
18 and or the Global Positioning System (GPS) Receiver.

19 The microprocessor is used to calculate the Cumulative
20 Leakage Index (CLI) or the Vehicular Leakage Index (VLI).
21 The components of the CLI are the RF signal level, the
22 distance from the coaxial cable, the frequency of the
23 signal, and the number of leaks per coax mile. The CLI is
24 calculated for a specific time period. The CLI is
25 calculated at three meters.

1 The present invention can calculate the CLI by placing
2 the vehicle at three meters from the leak. However, in use,
3 the present invention can also calculate a vehicular leakage
4 index (VLI).

5 The VLI is the same as the CLI with the average
6 distance from the antenna to the cable input by the
7 operator. The VLI can indicate the signal strength of the
8 signal at the vehicle. The VLI can also indicate the signal
9 strength that would occur if the antenna were at three
10 meters from the leak. The microprocessor will store data
11 when the 15.734 Khz signal is detected. The signal will be
12 stored but it may not be valid.

13 The microprocessor also calculates the Valid Signal
14 Detect level. The Valid Signal detect level is true when:
15 there is 4 to 6 dB difference between the peak and average
16 signal levels (indicating sync is present), the 15.734 Khz
17 sync level is true; then the computer switches the FM
18 Receiver up 4.5 MHz. After the 4.5 MHz switch, it again
19 stores the peak, average signal levels, and the 15.734 Khz.
20 The peak and average signal levels should now be the same
21 level and the 15.734 Khz should no longer be present. If
22 all of the above is true, the Valid Signal Detect Level will
23 be true.

24 A GPS Receiver is used to keep track of the location of
25 the vehicle when leaks were detected. The GPS Receiver is

1 also used to prove that the vehicle covered the assigned
2 route.

3 The deluxe control head contains the front panel
4 switches and displays - including the above mentioned Light
5 Emitting Diode (LED) meter. The LED meter is a logarithmic
6 meter. The meter displays a bar graph of the signal level
7 and has the capability to hold the peak RF level.

8 This capability gives the instrument the ability to see
9 both the sync and the video signals simultaneously, thus,
10 identifying the signal as television video. Also, this
11 capability gives the instrument the ability to identify
12 standing waves on the cable sheath. The leak will occur at
13 the maximum signal level observed by the operator as he
14 drives along the cable. This gives the operator the ability
15 to exactly locate the discontinuity in the coax cable
16 system. The LED meter also has its scale in color coded
17 LED's for ease of observation. Each LED has a range of 1/2
18 to two dB which gives the meter a total dynamic range of 20
19 to 80 dB. Up to 20 μ V/m the scale is green, from 21 μ V/m to
20 50 μ V/m the scale is yellow, and over 50 μ V/m the scale is
21 red. All of the leaks occurring in the yellow and red scale
22 should be fixed in order for the CATV system to be in
23 compliance with the FCC's signal leakage rules.

24 The fast ballistics of this meter allow the instrument
25 to locate a leak and display the peak reading, at any

1 vehicle speed. conventional mechanical meters do not have
2 the meter ballistics to indicate and hold peak levels, and
3 do not have the ability to display both peak reading by a
4 "flying dot", and average reading by a bar graph.

5 The antenna and electronics for the preferred
6 embodiment of the invention have the capability to detect
7 whether the leak is occurring on the left or right side of
8 the vehicle. The direction is displayed with left and right
9 indicator LED's. Additionally, the antenna has an
10 electronic gain control to allow the LED meter to indicate
11 properly with different ranges to the leaking cable. The
12 electronic gain control can add or subtract 20 dB of gain
13 from the system corresponding to ± 100 feet of effective
14 range. The electronic gain control can also be used to
15 increase the sensitivity to leaks when all of the higher
16 level leaks have been repaired.

17 An alpha numeric key pad can be interfaced with the
18 microprocessor and additional data can be input and stored
19 in the microprocessor's RAM. Additional information
20 concerning a RF leak can be input thru the keypad. Cause of
21 leak, resolution code of leak, materials used to fix leak,
22 and time, date, and name of repair technician can be input
23 for future reference.

24 In a typical cable system the more expensive embodiment
25 described above would be in a relatively few vehicles. A

1 less expensive embodiment would have the speedometer cable
2 interface to the microprocessor and record only RF leaks
3 with the 15,743Hz sync component of the video. It will also
4 record the miles covered by the vehicle. With the number of
5 leaks, peak RF levels of the leak, and miles driven a
6 "Vehicular Leakage Index" (VLI) can be computed. This
7 number when compared with itself over a period of time will
8 provide an indication of RF integrity. Leak index is a
9 measurement of RF signal leakage over time. If the Leak
10 Index is increasing over this specific time period as
11 compared to another time period, then the number and/or
12 level of leaks/mile is increasing. When the leaks are
13 recorded on a separate computer and data base, the total
14 number of leaks and their RF level, miles driven compared to
15 total system miles, the FCC method of calculating a CLI can
16 be used and reported to the FCC. The above embodiment could
17 use a less expensive antenna and electronics.

18 Another embodiment of the invention would use the above
19 system with a GPS or Loran Receiver. The specific location
20 of the leaks can be recorded. With location data, the
21 service personnel can be dispatched.

22 This system can also be used to detect scrambled
23 signals without any loss of sensitivity. A scrambled signal
24 has its vertical and/or horizontal sync pulse suppressed 6 -

1 10 dB. This is done to prevent unauthorized use of the
2 television signal.

3 BRIEF DESCRIPTION OF THE DRAWINGS

4 FIG. 1 is a general block diagram of the preferred embodiment of
5 the invention.

6 FIG. 2 is a more detailed block diagram of preferred embodiments
7 of the invention illustrating the interconnecting signals.

8 FIG. 3 is a block diagram of the antenna electronics.

9 FIG. 4 is a block diagram of the Deluxe Control Head.

10 FIG. 5 is an illustration of the front panel of the Deluxe
11 Control Head.

12 FIG. 6 is a block diagram of the VLI Receiver.

13 FIG. 7 is an isometric view of the antenna.

14 FIG. 8 is an isometric view of the antenna base with the antenna
15 in the down position.

16 FIG. 9 is an isometric schematic view of the antenna.

17 FIG. 10 is a side plane view of the antenna base in the up
18 position with a cutaway view of the antenna in the down position.

19
20
21
22 Before explaining the disclosed embodiment of the present

1 invention in detail, it is to be understood that the invention is
2 not limited in its application to the details of the particular
3 arrangement shown, since the invention is capable of other
4 embodiments. Also, the terminology used herein is for the
5 purpose of description and not of limitation.

DESCRIPTION OF PREFERRED EMBODIMENTS

Referring to FIG. 1 a simple block diagram for the preferred embodiment is shown. The preferred embodiment is an RF Leakage Detector (600) to be mounted in a vehicle (300). The vehicle (300) can drive at any speed and detect RF leaks from a coaxial cable system (not shown) or any other signal sources. The components of the RF Leakage Detector (600) are: the antenna system consisting of antennas (1, 2, and 6), the antenna switch box (500), the Deluxe Control Head (15), the keypad (13) and variable timer (14), the control unit (400) and the two-way radio adapter (19). The above assemblies are interconnected by cables (301 to 311). The Left Antenna (1) and Right Antenna (2) are used in conjunction with the antenna switch box (500) to detect an RF leak and the direction to the place in the coaxial cable (not shown) where the leak is occurring. The Deluxe Control Head (15) is used to display data and to input commands to the RF Leakage Detector (600). The keypad (13) is also used to input information to the RF Leakage Detector (600). The Control Unit (400) is equipped with a receiver (401) to detect the leaks, a GPS receiver (403) to obtain accurate position data, and a microprocessor (402) to

FOUO "SECRET"

1 control the RF Leakage Detector (600) and store the data.
2 The vehicle (300) has a sensor (not shown) on a wheel (9)
3 which can be used by the RF Leakage Detector (600) to obtain
4 speed and mileage information. The variable timer (14) can
5 direct the RF Leakage Detector to store data at regular
6 intervals. The radio adapter (19) is an interface to a two-
7 way radio (60) in order to receive commands from and send
8 data to a home base (not shown).

9 FIG. 2 is the functional block diagram of the Coaxial
10 Cable RF Leakage Detector (30).

11 The most important components of the Coaxial Cable RF
12 Leakage Detector (30) are the controller box(20), the
13 Receiver (25), and the Deluxe Control Head (15). Several
14 external devices have inputs to, or outputs from, these
15 three components.

16 The controller box (20) provides a great deal of
17 flexibility in the use and display of data from external
18 devices. The preferred embodiment will contain inputs from,
19 or outputs to, all of the following external devices;
20 however, other embodiments can be made up of any combination
21 of the following and other external devices.

22 The antenna system (1-5) has the capability to receive
23 RF energy from the left antenna (1) or the right antenna
24 (2). The antennas (1, 2) transmit the energy over coaxial
25 cables (3, 4) to the right/left antenna switch (5). The

1 Receiver (25) controls the right/left antenna switch (5).
 2 The output from the right/left antenna switch (5) antenna RF
 3 (A) goes to the Receiver (25).

4 The GPS antenna (6) is mounted with the left and right
 5 antennas (1, 2) and is connected to the GPS Receiver (8) via
 6 coaxial cable (7). The GPS Receiver provides position data
 7 to the controller box (20). The function of the GPS
 8 Receiver and antenna (6 - 8) can also be performed by a
 9 Loran Receiver and antenna (not shown).

10 The speed of the vehicle is sensed by a speedometer
 11 sensor (10) and cable (61) on the wheel (9) of the vehicle
 12 (not shown). A vehicle speedometer interface (11) to the
 13 speedometer cable (61) provides vehicle speed data to the
 14 controller box (20).

15 A keypad (13) is provided to input user data to the
 16 controller box (20). Additional information concerning an
 17 RF leak can be input through the keypad such as: cause of
 18 the leak; resolution code of the leak; materials used to fix
 19 leak; time; date; and name of repair technician.

20 A two-way radio adaptor (19) is provided to remotely
 21 control the Coaxial Cable Leakage Detector (30) via the
 22 controller box (20). The controller box (20) can both
 23 receive commands and send data via the two-way radio
 24 interface (19). The combination of the controller box (20),
 25 the two radio adaptor (19), and a two way radio (not shown)

1 forms a telemetry system for real time or delayed
2 transmission of data to and from the coaxial cable RF leakage
3 detector (30).

4 The controller box (20) can also send and receive data
5 via the data port (16), the auxiliary data port (17), the
6 map display screen (62), and other interface adapters (12).

7 The Coaxial Cable RF Leakage Detector (30) has a
8 Variable Timer Control (14) functioning to command the
9 controller box (20) to store data at specific time points
10 such as a 5 second, 30 second, 1 minute, or 1 hour schedule.
11 The Variable Timer Control (14) is used to keep a record of
12 the vehicle (not shown) location.

13 The Deluxe Control Head (15) is used for display and
14 command functions between the Deluxe Control Head (15), the
15 controller box (20), and the Receiver (25). The deluxe
16 control head (15) sends the DATA STORE (M) signal to the
17 controller box (20) and receives the LCD READOUT DATA (L)
18 and the GPS MICROPROCESSOR STATUS (K) from the controller
19 box (20). The deluxe control head sends three signals to
20 the Receiver (25): the DISTANCE TO CABLE (B), the PLL
21 FREQUENCY SELECT (C) and the AUDIO TYPE (N). The Receiver
22 (25) then sends the DISTANCE TO CABLE (B) and the PLL
23 FREQUENCY SELECT (C) signals on to the controller box (20).
24 The Receiver (25) generates the @DET (where the @ in front
25 of a signal name indicates a negative true logic signal)

FOR OFFICIAL USE ONLY

1 (D), the PEAK SIGNAL LEVEL (F) and the AVG SIGNAL LEVEL (G)
2 and sends them to both the controller box (20) and the
3 Deluxe Control Head (15). Three signals are generated in
4 the Receiver (25) and sent to the Deluxe Control Head (15):
5 the AM/FM AUDIO (H), the RIGHT INDICATOR (I), and the LEFT
6 INDICATOR (J).

7 Another feature of the VLI Receiver 30 FIG. 2 is that
8 it can detect leaks in the reverse system of a broad band
9 coaxial cable system. This can be done by the radio
10 dispatcher querying the subscriber data terminals and
11 setting the frequencies of the leakage detector (30) through
12 the two way radio adaptor (19) on a fixed schedule. The VLI
13 receiver can detect the reverse RF path frequencies along
14 with a time, date and GPS location stamp for later analysis.

15 An optional simple control head (70) can be used in
16 place of Deluxe Control Head (15). The simple control head
17 is driven by the audio alarm signal (P) and the LED alarm
18 signal (R) to light alarm light (71) and audio alarm (72).

19 A minimal system would include the simple control head
20 (70) the VLI receiver (25) and an antenna (1). Internal to
21 the controller box (20) are the microprocessor (21), the bus
22 (22) and memory devices such as a flash RAM (23), RAM (24),
23 ROM (26) and other storage devices (27). Also included in
24 the controller box (20) is a power supply (28) for

1 generating the appropriate electronics power from the
2 vehicle battery (not shown).

3 The function block diagram of the antenna (212) and
4 antenna electronics (213) is shown in FIG. 3. Two antenna
5 elements (201 and 202) are separated by a distance of $\frac{1}{4}$ of
6 the wave length of the signal of interest. A phasing line
7 (203) is positioned between the two antenna elements (201
8 and 202). A relay (S200) is positioned such that it can
9 switch to either side of the phasing line (203). A square
10 wave clock (205) drives the relay coil (204) switching the
11 relay switch (S200) back and forth between the two sides of
12 the $\frac{1}{4}$ wave phasing line (203). If a signal is coming from
13 the left and the relay (S200) is switched to antenna element
14 (201), then the signal will go through the antenna element
15 (201) to relay (S200) (i.e. 0° phase angle). The signal
16 will be delayed $\frac{1}{4}$ wavelength (90° phase angle) at antenna
17 element (202) due to the physical separation of the two
18 antenna elements (201, 202) and another $\frac{1}{4}$ wavelength (90°
19 phase angle) due to the phasing line (203) to arrive at the
20 relay with $\frac{1}{2}$ wavelength delay (180°) thus the two signals
21 from the two antenna elements (201, 202) will cancel.

22 If in the same situation the relay (S200) is switched
23 to antenna element (202), then the signal from antenna
24 element (201) will be delayed by $\frac{1}{4}$ wavelength (90°) at the
25 relay (S200) due to the phasing line (203). The signal from

1 antenna element (202) will be delayed $\frac{1}{4}$ wavelength (90°) due
 2 to the physical separation of the two antenna elements (201,
 3 202). Therefore, the two signals will add at the relay
 4 (S200) if they come from the proper direction and cancel if
 5 they come from the other direction. The RF signal (A) from
 6 Relay (S200) goes to the Receiver (25) of FIG. 2.

7 The AM audio (E) from the Receiver (25) goes to the L/R
 8 amplifier (207).

9 The L/R Amplifier (207) uses the left/right direction
 10 signal from the square wave clock (205) with the AM audio
 11 signal (E) from the receiver (25) to derive a right (I) and
 12 left (J) signal proportional to the signal strength of the
 13 RF energy from the two directions. The Indicator LED Driver
 14 (208) uses comparators to generate the Right (I) and Left
 15 (J) signals to drive the LED light bars (M5 and M6) or the
 16 front panel (15) of FIG. 5.

17 FIG. 4 is the functional block diagram of the Deluxe
 18 Control Head (15). FIG. 5 is a layout of the front panel of
 19 the Deluxe Control Head (15). For the following discussion
 20 of FIGS. 4, 5 a device with a letter and number in the
 21 designation appears in both figures (i.e. the device is on
 22 the front panel of the Deluxe Control Head (15)).

23 Referring next to FIGS.: 2, 4, and 5 the double pole
 24 double throw AUDIO TYPE Switch (S2) comprising switches S2A
 25 and S2B. S2A selects a ground (157), or +5 Volts dc (156)

1 to generate the AUDIO TYPE (H) signal to the Receiver (25).
 2 The AUDIO TYPE (H) signal will request the Receiver (25) to
 3 send FM audio on the AM/FM AUDIO (N) signal if the AUDIO
 4 TYPE (H) signal is a ground (157). If the AUDIO TYPE (H)
 5 signal is +5 Volts (156), the AM/FM AUDIO (N) signal will be
 6 AM. If switch S2B provides a ground to the frequency select
 7 switch (58) then the Receiver (25) will move up 4.5 MHz from
 8 the tuned channel to get the television audio and place it
 9 on the AM/FM AUDIO (N) signal.

10 The AM/FM AUDIO (N) signal from the Receiver (25) goes
 11 through the AUDIO MODE Switch (S1), a volume control (R2),
 12 and an audio amplifier (179) to speaker (A2). As previously
 13 discussed, when the AUDIO MODE Switch (S1) is in the AM/FM
 14 AUDIO position, the user will hear the audio selected by the
 15 AUDIO TYPE (S2) switch on speaker (A2). If the Audio Type
 16 (S2) switch is on 4.5 MHz FM the user will hear the audio of
 17 the tuned television channel. If the AUDIO TYPE (S2) is on
 18 FM the user will hear the output of the FM section of the
 19 Receiver (25). If the AUDIO TYPE (S2) switch is on AM the
 20 user will hear the 59.94 Hz "vertical sync buzz" of the
 21 tuned television channel or the sound of an AM carrier if
 22 the AM section of the Receiver (25) is tuned to an AM
 23 carrier.

1 The Average Signal Level (G) and the Peak Signal Level
2 (F), from the Receiver (25) go to the METER MODE (S3) and
3 the AUDIO MODE (S1) switches.

4 If the AUDIO MODE (S1) switch is in position "AUDIO S
5 METER", the Audio "S" Meter Driver (175) will generate a
6 tone with an amplitude proportional to the Peak Signal Level
7 (F). If the Horizontal Sync Detect (D) signal from the
8 Receiver (25) is true, then the "AND" gate (176) will allow
9 the Audio "S" Meter tone to go through the double pole
10 triple throw AUDIO MODE (S1) switch to the speaker (A2).

11 The AUDIO MODE (S1) switch has one more setting
12 "ALARM". If the AUDIO MODE (S1) switch is set to "ALARM",
13 the Peak Signal Level (F) will go to the Signal Alarm Level
14 Detector (162). The Signal Alarm Level Detector (162) is
15 set by the Alarm Level Set (S9) Thumb Wheel Switch. If the
16 Peak Signal Level (F) exceeds the alarm level and the
17 Horizontal Sync Detect (D) signal is true, then the "AND"
18 gate (170) will then signal Alarm Driver Amplifier (171) to
19 drive the AUDIO ALARM (A1). The sound of the AUDIO ALARM
20 (A1) will notify the operator that a valid leak exceeding
21 the alarm level has occurred.

22 If the @DET Signal (D) is true Driver (173) will light
23 the Detect (M4) Light Emitting Diode.

24 If the METER MODE (S7) switch is in the "RF" position,
25 then the METER DETECTOR (S3) switch can pass on the Average

1 Signal Level (G) or the Peak Signal Level (F) signals from
2 the Receiver (25) to the Light Emitting Diode Display Meter
3 (M1) .

4 The output of switches (S3 and S7) go to the Light
5 Emitting Diode Display meter through two paths. One, the
6 signal goes to the Peak Detector Hold Circuit (155)
7 controlled by the Peak Hold Switch (S4). Depending on the
8 setting of the Peak Hold Switch (S4), the Peak Detector Hold
9 Circuit (155) will hold the highest peak signal that has
10 occurred ("HOLD"), hold the highest peak signal that has
11 occurred in the last few seconds ("MOMENTARY"), or pass the
12 signal on unchanged ("OFF") .

13 From the Peak Detector Hold Circuit (155) the signal
14 goes through a log amplifier (153) and the Peak Signal Dot
15 Driver (151) to display the Peak of the incoming signal on
16 the Light Emitting Diode Display Meter (M1). The second
17 path takes the signal through another Log Amplifier (154)
18 and Bar Signal Dot Driver (152) to display the average of
19 the incoming signal simultaneously with the peak value of
20 the incoming signal on the Light Emitting Diode Display
21 Meter (M1). The Light Emitting Diode Display Meter (M1) has
22 a series of LED's in a line (to form a light bar(LB1)) .

23 The LED meter (M1) has its scale in forty color coded
24 LED's for ease of observation. Each LED has a range of one
25 half dB, one dB, one and one half dB or two dB which gives

1 the meter a total dynamic range of 20 dB to 80 dB. The
2 dynamic range of meter (M1) is set by switch (S20). Switch
3 (S20) provides a ground (157) to log amplifiers (153, 154)
4 to achieve the required gain change. Up to $20\mu\text{V/m}$ the scale
5 is green, from $21\mu\text{V/m}$ to $50\mu\text{V/m}$ the scale is yellow, and
6 over $50\mu\text{V/m}$ the scale is red. All of the leaks occurring in
7 the yellow and red scale should be fixed in order for the
8 CATV system to be in compliance with the FCC's signal
9 leakage rules.

10 The fast ballistics of this LED meter (M1) allow the
11 instrument to locate a leak and display the peak reading, at
12 any vehicle speed. Conventional mechanical meters do not
13 have the meter ballistics to indicate and hold peak levels,
14 and do not have the ability to display simultaneously peak
15 reading by a "flying dot", and average reading by a bar
16 graph.

17 In the event of a leak that is a TV signal the 15.734K
18 Hz sync signal will be 3 dB to 6 dB above the average video
19 as can be seen on the Light Emitting Display Meter (M1). If
20 the TV signal is a suppressed sync signal such as a
21 scrambled signal then the peak level should be the same as
22 the normal TV leak at the same distance but the average
23 level will higher by 2dB to 4dB.

24 The Frequency Select Switch (S8) is used to select the
25 frequency of the suspected leak. The Frequency Select

1 Switch (S8) generates the Frequency Select Signal (C) to the
2 Receiver (25). If the leak is a television channel, then
3 the Average Signal Level (G) is a television composite video
4 signal. If the composite video is selected, by the switches
5 (S3 and S7), and the Peak Detector Hold Circuit (155) is in
6 the momentary state, then the sync signal will show on the
7 Light Emitting Diode Display Meter (M1) as a peak and the
8 video will be displayed 3 dB to 6 dB lower than the sync
9 signal. The ability to see both the peak and average
10 signals simultaneously on the light Emitting Diode Display
11 Meter (M1) enables the operator to distinguish several types
12 of leaks from spurious noise. Composite video is described
13 above, a suppressed carrier or scrambled video will be
14 similar to composite video but will have a smaller
15 difference between sync and video, a carrier will have no
16 difference. The Meter Mode Switch (S7) can also send the
17 AM/FM Audio Signal (N) to the Light Emitting Diode Meter
18 (M1). The Amplifier (158) buffers the AM/FM Audio Signal
19 (N) for this purpose. The signal on the AM/FM audio signal
20 (N) may be spurious noise, if so the level will be visible
21 on the Light Emitting Diode Display Meter (M1) and heard on
22 speaker (A2).

23 The distance from the vehicle to the cable can be set
24 by the Distance to Cable Knob (R1) on the front panel (15).
25 The Distance to Cable Knob (R1) controls the Variable

1 Distance Emulation Switch (181) which generate the Distance .
2 (B) signal to the Receiver (25) and Controller box (20) .

3 The GPS Status (K) signal from the controller box (20)
4 drives the GPS Status Light Emitting Diode Display (M3) .
5 The GPS status (K) signal will indicate: GPS power OK, GPS
6 data stream, GPS searching, GPS lock, microprocessor memory
7 full, or GPS error.

8 The Front Panel (15) has a Right and Left RF Signal
9 Indicator (M5 and M6) which are driven by the Right (I) and
10 Left (J) signals from the Receiver (25) . The Right (I) and
11 Left (J) signals also drive the Right/Left antenna indicator
12 switch (6S) which generates the Left/Right antenna signal
13 (S) to the controller box (20) .

14 The user can signal the controller box (20) to store
15 data by operating the Data Store (S5) switch. The Data
16 Store Line (M) will be true when the Data Store (S5) switch
17 connects it to ground (157) . The controller box (20) can
18 send data to the Liquid Crystal Display (M2) and receive
19 information from the Display Mode (S6) momentary switch over
20 the LCD Data (L) signal. When the Display Mode (S6) switch
21 is pressed, the Liquid Crystal Display (M2) changes
22 functions. The displayed data is: miles that the vehicle
23 has been driven, number of leaks detected, peak leak
24 detected, and Vehicle Leakage Indicator. Other data can
25 also be displayed on the Liquid Crystal Display (M2) such as

1 common GPS functions like distance to waypoint, ground
 2 speed, etc. Messages from a dispatcher over the two-way
 3 radio adapter (19) could also be displayed on Liquid Crystal
 4 Display (M2)

5 Referring next to FIG. 6, the block diagram of the VLI
 6 receiver (25) is shown. The power supply (43) provides the
 7 necessary DC voltage for the electronics from the vehicle
 8 battery (not shown). The antenna RF (A) signal from the
 9 antenna goes through a bandpass filter (30) in series with
 10 two gain (32,34) and two attenuation stages (32,33) to the
 11 AM/FM and FSK receivers (35,51 and 53). The amount of
 12 attenuation in the attenuation stages (31,33) is controlled
 13 by a "Look Up Table" in the PROM Controlled Driver circuit
 14 (45). The PROM Driver circuit (45) also selects the
 15 frequency of the Programmable PLL Local Oscillator (44).
 16 The inputs to the "Look Up Table" are the Frequency Select
 17 (C) and Distance (B) signals from the Deluxe Control Head
 18 (15). The VLI receiver (25) can be programmed to detect a
 19 number of different types of RF leaks by the innovative use
 20 of the outputs of the AM, FM and FSK receivers (35, 51, and
 21 53). The frequency that the AM, FM and FSK receivers
 22 (35,51, and 53) are tuned to is controlled by the Frequency
 23 Select (C) signal via the PROM Controlled Driver Circuit
 24 (45) and the Programmable PLL Local Oscillator (44). The
 25 outputs of the three receivers (35,51 and 53) can be

1 selected by Sync jumper (54) and noise jumper (55). The
2 output of the AM Receiver (35) is the AM audio signal (E).

3 The Sync detector (36) and the noise detector (39) are
4 Phase locked loops (PLL). The PLL's can detect frequency,
5 amplitude, and/or phase information. A Sync Detector (36)
6 is used on the output of the Sync jumper (54) to detect the
7 15.734 Khz Horizontal Sync of a TV video. The frequency of
8 the Sync Detector (36) can be changed to detect other
9 signals. The output of the noise jumper (55) goes to the
10 noise detector (39) which is set at 8.0KHz for video but is
11 also adjustable for other signal sources. The audio type
12 (N) signal drives the coil (42) of a relay (40) to switch
13 (41) the AM/FM audio (H) signal between the outputs of the
14 Sync Jumper (54) or the FM Receiver (51). The output of FM
15 Receiver (51) drives the Signal Level Alarm Set Control (50)
16 which in turn generates the Audio Alarm (P) signal and the
17 LED Alarm (R) signal. The Audio Alarm (P) and LED Alarm (R)
18 signals are for the simple control head (not shown). The
19 output of the FM Receiver (51) drives the RF Level Peak
20 Calibration Control (47) to generate the Peak Signal Level
21 (F) signal for the Deluxe Control Head (15). Additionally,
22 the output of the FM Receiver (51) drives the RF Average
23 Filter (48) in series with the RF Average Calibration
24 Control (49) to generate the Average Signal Level (G) for
25 the Deluxe Control Head (15). The double pole double throw

Carrier Mode Switch (46) puts the VLI Receiver (25) in the CW or TV mode. The outputs of the Carrier Mode Switch (46), and the Sync Detector (36) and the Noise Detector (39) generate the @DET Signal (D) via logic gates (37, 38, and 52). The @DET Signal (D) will be true if the VLI Receiver (25) is in the TV mode (Carrier Mode Switch (46) on TV) and the Horizontal Sync is present and there is no output from the Noise Detector (39).

Next, referring to FIGS. 7, 8, 9, and 10 where the antenna assembly (800) is shown. The RF Leakage Detector (not shown) can use one or more of the Antenna Assemblies (800). The antenna assembly (800) is designed to magnetically attach to the top of a vehicle (not shown) and to allow deflection of the components of the antenna assembly (800) in response to a collision with a tree or other obstacle while in use. In a preferred embodiment of the invention the antenna assembly (800) will mount on a surface by means of four circular magnets (821, 822, 823), which are attached to a flexible base plate (826). Three of the magnets (822, 823 and one not visible in the drawing but in a symmetrical position with magnet (822), are mounted in the base plate (826) close to the mounting base of the antenna (820). The remaining magnet, magnet (821), is preferably mounted approximately 10 inches forward of the mounting base of the antenna (820). The flexible base plate (826) is preferably made of a flexible material that will follow contour to the top of the vehicle (not shown) and provide some spring effect to prevent the antenna

1 assembly (800) from being knocked form the vehicle in the event
2 of contract with a tree branch or other obstacle.

3 In a preferred embodiment of the mounting base of the
4 antenna (920), the mounting base (920) will consists of two
5 units: the outer housing (827) and the inner block (828). The
6 inner block pivotally supports the antenna mast (807), which is
7 preferably made of stainless steel. As shown on FIG. 10, an end
8 portion of the inner block (828) will preferably include a
9 rounded or cammed surface (829A) which can interact with a
10 damping means (834), which in a preferred embodiment will include
11 a section of resilient foam, rubber or the like, or mechanical
12 damping means. In order to allow the cammed surface (829A) to
13 cooperate with the damping means (834), the inner block (828) is
14 preferably allowed to pivot approximately 90 degrees about a
15 pivot pin (829) mounted through the outer housing (827) and the
16 inner block (828). The relationship of the cammed surface (829A)
17 and the pivot pin (829) is such that as the inner block pivots
18 towards the position outlined in dashed lines in FIG. 10, the
19 cammed surface extends further and further into the damping means
20 (834), so as to dampen the movement of the inner block as it
21 approaches the position shown in dashed lines.

22 The position of the inner block (828) will preferably be
23 maintained in the vertical position (shown in solid lines in FIG.
24 10) by two adjustable detent pins (831). The adjustable detent

1 pins (831) are compressed by guides (832) to snap into detents
2 (833) on either side of the inner block (828). In other words,
3 the detents (833) can accept the detent pins (831) in order to
4 hold the relative position of the inner block (828) relative to
5 the outer housing (827). In a preferred embodiment the detent
6 pins (831) are slidably supported within the outer housing (827).
7 A spring is used to bias the detent pins (831) to a position
8 where they protrude into area of the outer housing (827) that
9 accepts the inner block (828). The bias of the spring that pushes
10 the detent pins (831) may be adjusted by means of a screw or
11 similar adjustment (830). Additionally, the detent pins (831)
12 will have a rounded tip which allows them to slide in and out of
13 the detents (833) in response to a force through the inner block
14 (828). Thus the inner block (828) may be held in a desired
15 position when the detent pins (831) are nested within the detents
16 (833), and the inner block (828) will move away from this
17 position in response to a force through the inner block (828)
18 which causes the detent pins (831) to slide out of the detents
19 (833). The force sufficient to knock the inner block (828) out of
20 the detents (833) is set by adjustments (830) which control the
21 bias on the detent pins (831). The adjustments (830) may be set
22 such that the antenna assembly (800) will not be damaged or
23 knocked off of the vehicle (not shown) when the antenna collides
24 with a tree.

25 The damping means (834) in the outer housing (827) serves

1 to decrease the rate of travel of the stainless steel antenna
2 mast (807). The damping means (834) also absorbs some of the
3 shock when the inner block (828) hits the 90 degree position.
4 The pivot pin (829) is mounted eccentric to the radius (not
5 shown) of the bottom of the inner block (828) to provide a cam
6 action to progressively dampen the rate of travel of the
7 stainless steel antenna mast (807). The antenna assembly (800)
8 is operational in the upright position for horizontally polarized
9 signals. The antenna assembly (800) can also be operated in the
10 horizontal position for signals that are vertically polarized.
11 Another detent (not shown) holds the inner block (828) in the
12 horizontal position, adjustment (835) controls the holding force
13 of this detent (not shown).

14 In a preferred embodiment, two antenna rods (801, 802), each
15 preferably being approximately thirty six inches in length, are
16 mounted at the top of the antenna mast (807). The rods (801,
17 802) are separated and restrained by two plastic clamps (803,
18 804). The plastic clamps (803, 804) are held in place by an
19 aluminum cap (805) and fasteners (806). The antenna rods (801,
20 802) are mounted approximately one inch apart in the plastic
21 clamps (803, 804). When the vehicle is in motion, the electrical
22 and mechanical spacing of the antenna rods (801, 802) is
23 maintained by spacers (812, 813). The rods (801, 802) are
24 electrically attached to wires (810, 811) through a sliding
25 contact (not shown) within the plastic clamps (803, 804). The

described slidable adjustment of the antenna rods (801, 802) allows adjustment of the total span of the antenna for optimal reception of a desired frequency. Thus, the illustrated adjustment has been set such that the electrical contact is at the 30% point on the rods (801, 802) with 70% of the length of each rod (801, 802) extended in opposite directions, allowing reception of a desired wavelength (and hence corresponding frequency). The plastic clamps (803, 804) are hermetically sealed and house a balun (809) and an F connector (not shown) to connect to a coaxial cable (808). Another F connector (not shown) is mounted on the base plate (826) at the other end of the coaxial cable (808). The base plate (826) and the four magnets (821, 822, 823) are covered with an ABS formed plastic cover to protect the parts from the environment.

In a preferred embodiment the antenna rods (801, 802) have a bend radius at the tips (814) of the rods (801, 802) pointing up. These bends have been incorporated into the rods in order to allow the rods to bend away and slide over the surface of the vehicle in the event that the rods are forced onto the mounting surface on the vehicle as the mast and inner block (828) move relative to the outer housing (827) in response to a collision with a tree, for example. It is important to note that while the preferred embodiment includes bent tips on the rods (801, 802), it is also contemplated that the ends of the rods may simply include a wheel, skid pad, or similar means that will allow the

1 rods (801, 802) to slide over the surface of the vehicle as the
2 rods come down over the surface of the vehicle in response to a
3 collision.

4 Thus, the rate of travel of the stainless steel antenna
5 mast (807) is slowed by the damping means (834). When the tips
6 (814) of the antenna rods (801, 802) hit the top of the vehicle
7 (not shown) they slide along the vehicle roof and are prevented
8 from digging into the vehicle roof by the bend radius (8,14).
9 Also, the rods (801, 802) will provide a progressive spring
10 effect when first one, and then the other, rod (801, 802)
11 contacts the roof. A further spring effect occurs by the bending
12 of the flexible base (826). All of the above prevents damage to
13 the antenna assembly (800) and prevents the antenna assembly
14 (800) from being knocked off the vehicle when a tree strike
15 occurs. The antenna rods (801, 802) with the one inch spacing and
16 30%/70% configuration provides a frequency range of 110 MHZ to
17 160 MHZ with a band width of 50 MHZ with a VSWR of less than 3 to
18 1 and with a gain comparable to a dipole. Director elements and
19 reflector elements could be added to this configuration for a
20 better front to back ratio and a higher gain.

21 Referring now to FIG. 11, it will be understood that it is
22 contemplated that the instant invention may be used to pinpoint
23 cable leaks at a remote location. In FIG. 11 a vehicle (85) is
24 being used to carry the apparatus for remote leak detection, or

1 RF Leakage Detector (600) in the field. FIG. 11 shows a typical
2 installation used for distributing radio frequency signals by
3 cable (83). In this typical installation a signal is received by
4 a central distribution station (82) which then distributes the
5 signal to subscribers by means of cable with amplification
6 stations (84) at desired intervals. A branch of the cable (83)
7 reaches the subscriber location (86) where the signal is
8 processed by a decoder (87) or converter. However, as
9 illustrated, a section of the cable (83) includes a signal leak
10 (88), perhaps caused by a damaged cable or improper cable
11 connection or union. To pinpoint the location of the leak (88),
12 the operator would contact the central distribution station (82)
13 and request that a test signal (at a frequency that does not
14 deteriorate or interfere with other signals sent to the
15 subscriber) be sent to the subscriber's decoder (87). Once the
16 decoder (87) receives this test signal from the central
17 distribution station (82), the decodes (87) will emit a response
18 signal which is of a strength and frequency that is easily
19 detected by the RF Leakage Detector (600). Thus the operator in
20 the truck (85) may make repeated requests to emit the test signal
21 in order to iteratively refine the location of the leak relative
22 to the vehicle (85).

23 Thus it can be appreciated that the above described
24 embodiments are illustrative of just a few of the numerous
25 variations of arrangements of the disclosed elements used to

1 carry out the disclosed invention. Moreover, while the invention
2 has been particularly shown, described and illustrated in detail
3 with reference to preferred embodiments and modifications
4 thereof, it should be understood that the foregoing and other
5 modifications are exemplary only, and that equivalent changes in
6 form and detail may be made without departing from the true
7 spirit and scope of the invention as claimed, except as precluded
8 by the prior art.
